NWEA

The COVID-19 pandemic has been a seismic and on-going disruption to K-12 schooling. Using test scores from 5.4 million U.S. students in grades 3-8, we tracked changes in math and reading achievement across the first two years of the pandemic. Average fall 2021 math test scores in grades 3-8 were .20-27 standard deviations (SDs) lower relative to same-grade peers in fall 2019, while reading test scores decreased by $.09-18$ SDs. Achievement gaps between students in low-poverty and high-poverty elementary schools grew by $.10-.20$ SDs, primarily during the 2020-21 school year. Observed declines are more substantial than during other recent school disruptions, such as those due to natural disasters.

#### Abstract

The COVID-19 pandemic has been a seismic and on-going disruption to $\mathrm{K}-12$ schooling. Using test scores from 5.4 million U.S. students in grades 3-8, we tracked changes in math and reading achievement across the first two years of the pandemic. Average fall 2021 math test scores in grades 3-8 were .20-27 standard deviations (SDs) lower relative to same-grade peers in fall 2019, while reading test scores decreased by $.09-.18$ SDs. Achievement gaps between students in lowpoverty and high-poverty elementary schools grew by .10-. 20 SDs, primarily during the 2020-21 school year. Observed declines are more substantial than during other recent school disruptions, such as those due to natural disasters.

## Background

Since the COVID-19 pandemic began in March 2020, educators, parents, and policymakers have been concerned about potential lost learning associated with on-going disruptions to schooling. Initial predictions drawing from research on summer learning loss, school disruptions due to inclement weather, and absenteeism research projected that students would not acquire $30-50 \%$ of their expected learning due to the spring 2020 school closures (Kuhfeld et al., 2020a). Researchers and educators also expected pandemic shocks to widen existing educational inequalities. For example, a survey of education researchers in November 2020 predicted that large increases in achievement gaps between low- and high-income students (from a pre-pandemic gap of 1.0 SD to 1.30 SD in math and 1.25 SD in reading) in elementary school would be observed by spring 2021 (Bailey et al., 2021).

Assessment data collected during the 2020-21 school year provides an initial understanding of student achievement during the early stages of the COVID-19 pandemic. In some cases, related research has relied on state summative assessments, with results indicating larger declines in math than reading between spring 2019 and 2021 (Halloran et al., 2021; West et al., 2021; Thorn \& Vincent-Horn, 2021). However, many critics have cautioned against interpreting trends in achievement test results between 2019 and 2021 due to differences in (a) testing population (Ho, 2020), (b) test mode of administration (Barnum, 2021), and (c) the length and content of the tests themselves (Gerwetz, 2021). In other cases, interim achievement tests have been used to examine student growth, including during the 2020-21 school year. For example, Lewis et al. (2021) showed that, although the average student demonstrated positive gains in math and reading during the 2020-21 school year, students were still behind typical (prepandemic) averages by spring 2021. Finally, both summative and interim tests show preliminary
evidence of widening achievement gaps by income and race/ethnicity (Halloran et al., 2021; West et al., 2021; Thorn \& Vincent-Horn, 2021), though these studies are not able to differentiate the period(s) in which gaps widened the fastest.

These initial findings coalesce on a similar story, but important gaps remain in our understanding of how COVID-19 has affected achievement. First, while evidence suggests that students began the 2020-21 school year less prepared than in prior years (Kuhfeld et al., 2020b), little is known about how prepared students were when they entered school in fall 2021, relative to both the fall of 2020 (directly following the pandemic's onset) and the fall of 2019 (prior to the emergence of COVID-19). Such information can help educators and policymakers contextualize the academic challenges that students currently face and, hopefully, provide data germane to addressing those challenges. Second, while many researchers anticipated incomebased achievement gaps widening approximately $25-30 \%$ by spring 2021 (Bailey et al., 2021), little is known about how these forecasts played out, including how gaps have changed over the entire scope of the pandemic thus far. ${ }^{1}$

## This Study

This brief uses new achievement data from fall 2021 (as well as fall data from the two prior years) to examine how student reading and math achievement at the beginning of the school year has changed across the course of the COVID-19 pandemic thus far. Using data from over 5.4 million students in grades 3-8 who took MAP Growth assessments in reading and math, we compared test scores for students in fall 2021 relative to same-grade peers in fall 2020 and

[^1]fall 2019 in 12,000 schools that administered MAP Growth assessments consistently across all three pandemic-impacted school years (2019-20, 2020-21, 2021-22). We addressed two research questions:

1) Have test scores decreased during the first two years of the pandemic (e.g., comparing 3rd grade achievement in fall 2019 and fall 2021)? If so, is that decline attributable to drops occurring (a) in the early phase of the COVID-19 pandemic immediately following school closures or (b) during the 2020-21 school year?
2) Did achievement gaps by school poverty widen following the onset of the COVID-19 pandemic? If so, did gaps primarily increase (a) in the early phase of the COVID-19 pandemic immediately following school closures or (b) during the 2020-21 school year?

## Results

## Math achievement dropped across the first two years of the pandemic, while reading

 achievement dropped primarily between fall 2020 and fall 2021Figure 1 presents changes in average test scores in SD units ${ }^{2}$ in fall 2020 and fall 2021 relative to fall 2019. Depending on grade, math test scores were .11-. 18 SDs (the value denoted by the green bars) lower in fall 2020 relative to fall $2019^{3}$, and then decreased an additional .09. 13 SDs by fall of 2021 (the difference between the green and purple bars). These results imply that the first and second year of the COVID-19 pandemic each resulted in similar math declines, and that students continue to begin the school year less prepared in each year since the pandemic

[^2]began. Meanwhile, reading shows a notably different pattern across the two years. Specifically, students showed mostly similar performance in fall 2020 compared to their same-grade peers before the pandemic (changes ranging from -. 02 to .05 SDs by grade). However, sizable drops occurred between fall 2020 and fall 2021 ( .13 to .23 SDs).

## Achievement gaps between low- and high-poverty schools widened in elementary grades and gaps increased primarily during the 2020-21 school year

Figure 2 displays changes in achievement gaps for low-poverty versus high-poverty schools between fall 2019 and fall 2021 (see online supplemental materials for calculations). Prior to the pandemic (e.g., fall 2019), there was already approximately a 1 SD difference in achievement between students in low- and high-poverty schools in both subjects (denoted by the circle at the base of the arrow) ${ }^{4}$. In the elementary school grades, these gaps are now approximately $20 \%$ wider in math and $15 \%$ wider in reading relative to before the pandemic (corresponding to a . 20 SD change in math and . 13 SD change in reading). However, changes in gaps by school poverty were much more modest in the middle school grades.

We also investigated the timing of when the school poverty achievement gap widened. Figure 3 displays the changes in average performance by school poverty level during the early stages of the pandemic (fall 2019 versus fall 2020) and the 2020-21 school year (fall 2020 versus fall 2021). While students in both low- and high-poverty schools showed declines in math following the onset of the pandemic, there are striking differences in the patterns observed during the 2020-21 school year by school poverty. Test scores continued to slide considerably for students in high-poverty elementary schools between fall 2020 and fall 2021 while they declined much more modestly in low-poverty elementary schools. In reading, both groups held

[^3]steady between fall 2019 and fall 2020 and then showed sizable declines between fall 2020 and fall 2021, with moderately larger declines for students in high-poverty schools such that gaps widened.

## Discussion

The COVID-19 pandemic represents an unprecedented interruption to students' lives and schooling experiences, so it is perhaps not surprising that large academic declines were observed during this period. We found that average same-grade math test scores dropped by .20-.27 standard deviations (SDs) between fall 2019 and fall 2021. These drops are significantly larger than estimated impacts from other large school disruptions, such as after Hurricane Katrina (Sacerdote [2012] when reported math scores dropped . 17 SDs in one year for New Orleans evacuees). Further, while reading declined little between fall 2019 and 2020, suggesting that the effects of the early phase of the pandemic were mainly on math, large declines emerged between fall of 2020 and 2021, suggesting that reading has also been negatively impacted. While we should not speculate about the potential causes of the decline in reading between fall of 2020 and 2021, understanding it will likely be vital to helping students catch up as they continue to move through school.

Second, we show that, as hypothesized by educational researchers (e.g., Bailey et al., 2021), income-based gaps have indeed expanded substantively during the COVID-19 pandemic. In the elementary grades (where widened gaps were most evident), gaps increased by roughly $20 \%$ in math and $15 \%$ in reading. These estimates are similar to, but slightly lower than, researcher's projections (though one should note we are limited to using school poverty rather than student-level socioeconomic status [SES] in these analyses). However, our results corroborate the prediction that math would be more impacted than reading (both in terms of
overall achievement declines and widening of achievement gaps). Although speculative, this is possibly because parents have more capacity to support learning in reading and are more likely to routinely engage their children with reading as opposed to math learning (Sawchuk \& Sparks, 2020).

The widening of income-based gaps is in part attributable to differential patterns in how test score declines have accumulated across the scope of the pandemic. Specifically, during the 2020-21 school year, high-poverty schools continued to experience declines in math and had larger losses in reading, whereas low-poverty schools avoided further losses in math and saw less severe losses in reading. The result is that the pandemic has taken a larger toll on students in high-poverty schools. Thus, educators working in high-poverty schools likely have an even more difficult task to address the effects of COVID-19. Since students in poorer communities have also likely been impacted more by economic, health, and socio-emotional effects from the pandemic (West et al., 2021; Thorn \& Vincent-Lancrin, 2021), policymakers may wish to consider what additional resources are needed to support teachers serving the nation's lowest income-and potentially most vulnerable-students.

Figure 1
Trends in MAP Growth test scores in fall 2020 and fall 2021 (relative to same-grade peers in fall 2019)

Note. Reported estimates are calculated based on the fall 2019 mean and standard deviation (SD) in a given grade/subject.

Note. Reported gaps (in standard deviation units) are between students in low- and high-poverty schools, where low-poverty schools are schools with free or reduced priced lunch [FRPL] eligibility less than $25 \%$ in 2019-20, while high-poverty schools are schools with free or reduced priced lunch [FRPL] eligibility greater than or equal to $75 \%$ in 2019-20. Achievement gaps by school poverty level in fall 2019 are reported as a circle, while achievement gaps in fall 2021 are reported as the arrowhead. Changes between fall 2019 and fall 2021 are shown as the proportional increase or decrease, calculated by taking the difference in the standardized gaps between years and dividing by the fall 2019 standardized gap. Estimated gaps are reported in Table 6.

Figure 3. MAP Growth test score in fall 2019, 2020, 2021 by school poverty in math and reading
(A) Math

Note. Low-poverty schools are schools with free or reduced priced lunch (FRPL) eligibility less than $25 \%$ in 2019-20, while high-poverty schools are schools with FRPL eligibility greater than or equal to $75 \%$ in 2019-20. Mean scores are shown on the y-axis in RIT units, while differences across time within each school poverty level (fall 2019 vs. fall 2020 and fall 2019 vs. fall 2021) are reported in standardized units (relative to the 2019 mean and standard deviation for each group). Grade level is shown to the left of each line (for parsimony, only grades that typically correspond to elementary school are shown).

## Supplemental Materials - Description of Sample and Methodology

## Sample

The data for this study are from the NWEA anonymized longitudinal student achievement database. School districts use NWEA MAP® Growth ${ }^{\text {TM }}$ assessments to monitor elementary and secondary students' reading and math growth, with assessments typically administered in the fall (usually between August and November), winter (usually December to March), and spring (late March through June). The NWEA data also include demographic information, including student race/ethnicity, gender, and age at assessment. An indicator of student-level socioeconomic status is not available.

In total, our sample consists of approximately 5.4 million students in grades 3-8 in approximately 12,000 public schools who took MAP Growth reading and math assessments in fall 2019, fall 2020, and/or fall 2021. We limited our sample of schools to a consistent set of U.S. public schools that tested at least ten students in a given grade in fall 2019, fall 2020, and fall 2021. This sample restriction guards against the competing explanation that any differences we observe in achievement over time are potentially driven by systematic differences between schools that did and did not consistently test students in both years. Descriptive information for the students in our sample by grade/subject is provided in Table 1. Overall, the samples of students who tested in 2019 and of same-grade students who tested in fall 2021 were very similar in terms of gender and race/ethnicity, though the number of students tested in each grade was consistently larger in fall 2019.

Descriptive information for the schools in our math and reading samples along with comparison information on the population of U.S. schools is provided in Table 2. Information about U.S. public schools was obtained from the 2019-20 Public Elementary/Secondary School

Universe Survey data file. We define the population of interest as the set of US operational (e.g., school status variable SY_STATUS does not indicate the school is closed or yet to be opened) public schools in the 50 states and District of Columbia serving students in a given grade (based on the GX_OFFERED variable equal to "Yes"). The schools in our sample represent roughly 12$15 \%$ of U.S. public schools in any given grade. NCES school characteristics included in our comparison include enrollment by grade, percentage of students receiving free or reduced-price lunch (TOTFRL divided by school enrollment), and percentages of the students in the school who were Hispanic, Black, and White, and Asian (HI, BL, WH and AS) divided by total enrollment, and urbanicity (NCES' LOCALE codes, collapsed into City, Suburb, Town, and Rural).

Our sample closely matches the national distribution of schools across various locales (urban, suburban, rural, and town). However, our sample reflects schools serving higher average percentages of white students ( $55 \%$ in our sample vs. $49 \%$ in the nation), lower average percentages of Hispanic students ( $20 \%$ vs. $26 \%$ ), and slightly lower percentages of students eligible for FRPL relative to national averages ( $53 \%$ vs. $56 \%$ ).

## Measure

Student test scores from the NWEA MAP Growth reading and math assessments, called RIT scores, were used in this study. MAP Growth is a computer adaptive test that precisely measures achievement even for students above or below grade level and is vertically scaled to allow for the estimation of gains across time. The MAP Growth assessments are typically administered three times a year (fall, winter, and spring) and are aligned to state content standards (NWEA, 2019). Test scores are reported on the RIT (Rasch unIT) scale, which is a linear transformation of the logit scale units from the Rasch item response theory model. We also
reported scores in standard deviation units, which are described in further detail in the following section.

## Methodology

RQ1: How did math and reading achievement change during the first and second year of the COVID-19 pandemic? To understand how achievement in fall 2020 and fall 2021 compared to prior to the pandemic (e.g., fall 2019), we standardized the fall 2020 and fall 2021 test scores relative to the mean and standard deviations (SDs) of the fall 2019 MAP Growth test scores (separately by grade level). The resulting estimate $\overline{\mathrm{Z}}_{21 \mathrm{~g}}$ represents the standardized difference (in fall 2019 SDs) between the fall 2019 and fall 2021 means:

$$
\overline{\mathrm{Z}}_{21 g}=\frac{\overline{\mathrm{RIT}}_{21 g}-\overline{\mathrm{RIT}}_{19 g}}{\mathrm{SD}_{19 g}}
$$

Standardized mean estimates were calculated in fall 2020 and fall 2021 for each grade/subject. The mean and SDs used to calculate the standardized estimates are reported in Table 3 (math) and Table 4 (reading). The standardized differences are reported in Table 5. Changes in mean RIT scores across years (as well as the standardized differences) are also shown in Figure A1.

RQ2: Did achievement gaps by race/ethnicity and school poverty widen during the pandemic? Similarly, to understand group differences across time, we translated all the subgroup RIT score means into the same standardized unit based on the overall fall 2019 mean and SD. In 2019, the estimate $\overline{\mathrm{Z}}_{19 s g}$ in grade $g$ and subgroup $s$ represents the difference in SDs between the fall 2019 subgroup mean and the overall mean in fall 2019:

$$
\overline{\mathrm{Z}}_{19 s g}=\frac{\overline{\mathrm{RIT}}_{19 s g}-\overline{\mathrm{RIT}}_{19 g}}{\mathrm{SD}_{19 g}}
$$

In fall 2021, the estimate $\overline{\mathrm{Z}}_{21 s g}$ in grade $g$ and subgroup $s$ represents the difference in SDs between the fall 2021 subgroup mean and the overall mean in fall 2019:

$$
\overline{\mathrm{Z}}_{21 s g}=\frac{\overline{\mathrm{RIT}}_{21 s g}-\overline{\mathrm{RIT}}_{19 g}}{\mathrm{SD}_{19 g}} .
$$

Figure A2 displays a comparison of standardized mean test scores in low-poverty and highpoverty schools across fall 2019 , fall 2020, and fall 2021 . Figure A3 shows changes in average RIT scores by school poverty level across the three school years, as well the changes across time within school poverty level in standard deviation units.

Additionally, we calculated the standardized gap between average test scores in grade g in each year. For example, the standardized gap for White and Black students in grade $g$ in fall 2019 is

$$
\mathrm{ES}_{B W, 19 g}=\frac{\overline{\mathrm{RIT}}_{19 \mathrm{Bg}}-\overline{\mathrm{RIT}}_{19 \mathrm{Wg}}}{\sqrt{\frac{\left(\mathrm{~N}_{19 \mathrm{Bg}}-1\right) \mathrm{SD}_{19 B g}^{2}+\left(\mathrm{N}_{19 W g}-1\right) \mathrm{SD}_{19 W g}^{2}}{\mathrm{~N}_{19 B g}+\mathrm{N}_{19 \mathrm{Wg}}-2}}},
$$

where $\overline{\mathrm{RIT}}_{19 \mathrm{~B} g}$ is the average fall 2019 Black test score in grade $\mathrm{g}, \overline{\mathrm{RIT}}_{19 \mathrm{~W} g}$ is the average fall 2019 White test score in grade $\mathrm{g}, \mathrm{SD}_{19 \mathrm{Bg} g}$ and $\mathrm{SD}_{19 \mathrm{~W} g}$ are the corresponding SD estimates, and $\mathrm{N}_{19 \mathrm{Bg}}$ and $\mathrm{N}_{19 \mathrm{Wg}}$ are the observed sample size in grade g in fall 2019 for Black and White students respectively. Table 6 displays standardized achievement gaps between White and Black students, White and Hispanic students, and low- and high-poverty school students in fall 2019, fall 2020, and fall 2021.

## Limitations

There are several important limitations worth noting. Most importantly, we only included schools that tested in fall 2019, fall 2020, and fall 2021. Schools that consistently tested across this three-year span are likely different from schools that tested in just one or the other year. Given the composition of the schools that met our inclusion criteria and the stability inherent in testing consistently across a three-year span, we expect achievement declines in the schools
excluded from our sample would be more severe than what is reported here. Second, higher attrition rates have been documented during the pandemic than in prior years (Kuhfeld et al., 2020b; Schweig et al., 2022). While the demographic characteristics of our sample remain highly consistent across the three testing periods (see Table 1), it is possible that changes in test-taking populations across years that were not captured by the small number of student characteristics we observed could have occurred. Additionally, the number of students testing in a grade seems to have disproportionately dropped between fall 2019 and fall 2021 in high-poverty schools relative to low-poverty schools (see Table 7). For example, the number of $3^{\text {rd }}$ graders taking the math assessment in fall 2021 was nine percent lower than the number testing in fall 2019 in highpoverty schools, but only $3.6 \%$ lower in low-poverty schools. If the missing students in highpoverty schools were disproportionately low-achieving, we may be underestimating the achievement gaps by school poverty in fall 2021.

Third, we did not have access to information in fall 2020 on whether students were assessed in-person or remotely, nor do we know whether students had access to in-person, hybrid, or remote instruction through the course of the 2020-21 school year. While other recent work has examined differences in 2021 proficiency rates by access to in-person access (e.g., Halloran et al., 2021), we did not have enough detailed information about in-person instruction availability and attendance to conduct similar analyses. Finally, we have access to limited demographic information on students and are unable to disaggregate our data by student-level poverty, English Language status, or special education status.

Note: FRPL=free or reduced priced lunch. The reported samples represent the set of schools that tested at least ten students in a grade in fall 2019, fall 2020, and fall 2021. The sources of the variables are the Common Core of Data (CCD) collected by the National Center for Educational Statistics. The U.S. public school population comparison for each grade was determined by limiting to the schools that were operational in the 2019-20 school year and enrolled students in that grade level.

| 4 | Low Poverty | 0.49 | 0.34 | 0.32 | 0.44 | 0.47 | 0.34 |
| 5 | Low Poverty | 0.51 | 0.39 | 0.34 | 0.45 | 0.45 | 0.35 |
| 6 | Low Poverty | 0.53 | 0.38 | 0.36 | 0.47 | 0.47 | 0.38 |
| 7 | Low Poverty | 0.54 | 0.38 | 0.31 | 0.47 | 0.48 | 0.38 |
| 8 | Low Poverty | 0.55 | 0.38 | 0.27 | 0.46 | 0.47 | 0.38 |

Note. All estimates are calculated by subtracting the observed mean for a given year/subject/grade by the fall 2019 overall sample mean and dividing by the overall sample SD in a given grade.

Table 6
Achievement Gaps by School Poverty Across Years

|  |  | Low-High School Poverty Gap |  |  |
| :--- | :--- | :--- | :--- | :--- |
| Subject | Grade | Fall 2019 | Fall 2020 | Fall 2021 |
| Math | 3 | 0.94 | 0.90 | 1.12 |
| Math | 4 | 0.94 | 0.98 | 1.13 |
| Math | 5 | 0.97 | 1.02 | 1.16 |
| Math | 6 | 1.05 | 1.01 | 1.13 |
| Math | 7 | 1.09 | 1.01 | 1.10 |
| Math | 8 | 1.11 | 1.00 | 1.06 |
| Reading | 3 | 0.88 | 0.90 | 1.00 |
| Reading | 4 | 0.89 | 0.98 | 1.03 |
| Reading | 5 | 0.91 | 1.00 | 1.04 |
| Reading | 6 | 0.95 | 0.98 | 1.01 |
| Reading | 7 | 0.96 | 0.94 | 0.99 |
| Reading | 8 | 0.96 | 0.93 | 0.96 |

Table 7
Comparison of Sample Size Changes Across Years by School Poverty Level

| Grade | Subject | School Type | Fall 2019 Sample Size | Fall 2019 - Fall 2020 |  | Fall 2019 - Fall 2021 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Change in \# of students testing | \% change | Change in \# of students testing | \% <br> change |
| 3 | Math | High Poverty | 143,812 | -15,799 | -11.0 | -12,969 | -9.0 |
| 4 | Math | High Poverty | 146,650 | -16,755 | -11.4 | -15,110 | -10.3 |
| 5 | Math | High Poverty | 149,961 | -19,889 | -13.3 | -20,598 | -13.7 |
| 6 | Math | High Poverty | 125,573 | -20,767 | -16.5 | -14,761 | -11.8 |
| 7 | Math | High Poverty | 119,469 | -18,078 | -15.1 | -10,548 | -8.8 |
| 8 | Math | High Poverty | 109,159 | -15,993 | -14.7 | -6,954 | -6.4 |
| 3 | Math | Low Poverty | 125,395 | -7,285 | -5.8 | -4,466 | -3.6 |
| 4 | Math | Low Poverty | 125,680 | -5,429 | -4.3 | -3,812 | -3.0 |
| 5 | Math | Low Poverty | 128,810 | -6,686 | -5.2 | -3,415 | -2.7 |
| 6 | Math | Low Poverty | 120,765 | -9,207 | -7.6 | -7,736 | -6.4 |
| 7 | Math | Low Poverty | 115,134 | -9,421 | -8.2 | -4,133 | -3.6 |
| 8 | Math | Low Poverty | 103,320 | -12,440 | -12.0 | -7,687 | -7.4 |
| 3 | Reading | High Poverty | 129,064 | -10,272 | -8.0 | -10,854 | -8.4 |
| 4 | Reading | High Poverty | 131,210 | -12,473 | -9.5 | -18,725 | -14.3 |
| 5 | Reading | High Poverty | 129,983 | -14,581 | -11.2 | -27,327 | -21.0 |
| 6 | Reading | High Poverty | 113,235 | -17,114 | -15.1 | -19,954 | -17.6 |
| 7 | Reading | High Poverty | 109,696 | -13,957 | -12.7 | -16,526 | -15.1 |
| 8 | Reading | High Poverty | 99,413 | -10,139 | -10.2 | -12,037 | -12.1 |
| 3 | Reading | Low Poverty | 117,068 | 220 | 0.2 | -6,251 | -5.3 |
| 4 | Reading | Low Poverty | 113,408 | 1,769 | 1.6 | -9,720 | -8.6 |
| 5 | Reading | Low Poverty | 116,257 | -1,246 | -1.1 | -13,012 | -11.2 |
| 6 | Reading | Low Poverty | 105,109 | -133 | -0.1 | -10,999 | -10.5 |
| 7 | Reading | Low Poverty | 101,656 | 905 | 0.9 | -7,549 | -7.4 |
| 8 | Reading | Low Poverty | 95,126 | 3,915 | 4.1 | -1,948 | -2.0 |

Note. The number of students tested in each term by school poverty, grade, and subject is reported in Tables 3 and 4 . Percent change in the number of students tested is calculated by dividing the change in number of students testing in a grade/subject/school poverty level between falls by the number of students tested in fall 2019.

Figure A1. MAP Growth mean test score in fall 2019, 2020, 2021 in math and reading (A) Math

(B) Reading

Note. Mean scores are shown as points in RIT units, while differences across time (fall 2019 vs. fall 2020 and fall 2019 vs. fall 2021) are reported in standardized units (relative to the 2019 M/SD).

Figure A2. MAP Growth test score in fall 2019, 2020, 2021 by school poverty in math (left panel) and reading (right panel).
(A) Math

(B) Reading

Note. Reported estimates are calculated based on the fall 2019 overall sample mean and SD in a given grade. Low-poverty schools are schools with free or reduced priced lunch [FRPL] eligibility less than $25 \%$ in 2019-20, while high-poverty schools are schools with free or reduced priced lunch [FRPL] eligibility greater than or equal to $75 \%$ in 2019-20.

[^1]:    ${ }^{1}$ Bailey et al. (2021) asked researchers to forecast individual-based income achievement gaps. While some research studies have examined achievement gaps by school poverty since the start of the pandemic (e.g., Lewis et al., 2021; West et al., 2021), none of the studies we are aware of were scaled in a way that allow for comparisons with the Bailey et al.'s (2021) projections (e.g., estimates were reported as percentile changes rather than standardized test scores). We are unaware of any current research using spring 2021 test scores and individual income data.

[^2]:    ${ }^{2}$ Test scores are standardized relative to the mean and standard deviation (SD) observed in our sample in fall 2019 (separately by grade and subject). See the supplemental materials for a description of the assessment, sample, and methods.
    ${ }^{3}$ See Johnson, Kuhfeld, and Tarasawa (2021) for a discussion of the accuracy of Kuhfeld et al. (2020a)'s "COVID Slide" projections, which predicted students would likely return in fall 2020 with $63-68 \%$ of a typical year's learning (depending on grade) in reading and $37-50 \%$ in math. While fairly typical reading gains were observed by fall 2020 (exceeding the projections), students started fall 2020 having made $34 \%-80 \%$ of prior-year math learning gains on average.

[^3]:    ${ }^{4}$ Bailey et al. (2021) similarly reported a pre-pandemic achievement gap of 1SD between elementary-aged students in the bottom and top income quintile.
